The D-1 receptors are linked to dopamine-sensitive adenylate cyclase, while the D 2 receptors are those that are not linked to this enzyme. It appears necessary to modify this terminology because there is no biochemically practical method for determining the proportion of linked and nonlinked dopamine receptors and there is no relation between the behavioral potencies of dopamine agonists or antagonists and their potencies on this enzyme.

Five subtypes of mammalian dopamine receptors have been identified that are divided into D1-like (D1 and D5) or D2-like (D2, D3, and D4) groups. The D1-like receptors couple primarily to the G α s family of G proteins (G α s and G α olf), whereas the D2-like receptors couple primarily to the G α i/o family.

D1 dopamine (DA) receptor antagonist SCH 23390 stimulated a number of studies on the functions mediated by central DA receptor subtypes. It was generally assumed that the central D1 DA receptor is a molecular entity whose function awaits further discovery.
